

Using AI to draft KQL and SPL queries

By Jack Peduzzi

What are SPL and KQL Queries?

- Kusto Query Language (KQL) is a powerful language that is used within a variety of Microsoft products. This includes Sentinel, Azure Data Explorer, Microsoft Fabric, and Azure Monitor
- KQL is used to query structured, semi-structured, and unstructured data
- It is a read-only request to process results and data
- Splunk Processing Language (SPL) is used within Splunk to search and visualize data.
- It uses a pipeline | to separate data and to show where the output of one command goes.
- KQL queries are long but here are a few important phrases: where, extend, summarize
- Example: `index=web_logs | sort status`

How can AI help?

- AI can help analysts write queries to fetch specific data. It can be used in conjunction with a strong technical and educational background.
- Make sure you understand what query the AI gives you
- A lack of understanding can lead to errors and misconfigurations.
- Be aware that AI can be wrong. It does not think for itself. Therefore, you must always verify that what it outputs will be correct

How KQL and SPL queries can be used in banking

- Both of these query types can be used extensively in the banking industry.
- With the help of AI, analysts can pick out data they want to visualize and learn more about.
- Banks often use Azure Data Explorer to see a large amount of data
- Using KQL queries, data analysts are able to spot evidence of fraud and analyze patterns over a period of time
- SPL queries are used in a SIEM. SOC analysts can use these powerful queries to help filter alerts to better understand an incident, or be able to see patterns that may show up over time.
